Improving the health and well-being of mothers and infants, one of the strategic priorities set forth in *Healthy Chicago*, is essential to becoming our nation's healthiest city. I'm pleased to present Births in Chicago, 1999-2009, which tracks Chicago's progress in maternal and child health and points to areas in need of improvement.

This report provides a comprehensive analysis of indicators related to maternal demographic characteristics, maternal health and medical services utilization, and infant health characteristics from 1999 to 2009. The data demonstrate that Chicago has made progress in many areas, including increases in rates of women receiving prenatal care and decreases in teen births and smoking during pregnancy. Despite these successes, disparities exist among racial-ethnic groups and there were limited improvements in preterm and low birthweight births.

Through the strategies outlined in *Healthy Chicago*, the Chicago Department of Public Health (CDPH) is committed to reducing the teen birth rate and rate of low birthweight babies by 10%. These goals will be accomplished, in part, through the work of our Office of Adolescent and School Health and Women and Children's Health Division, which includes such efforts as our Teen Pregnancy Prevention Initiative, conducted in partnership with Chicago Public Schools, and home visiting to pregnant and new mothers in Chicago. The work of our community partners remains critical to reaching our goals.

The data in this report will assist CDPH and community partners in tracking progress and developing the targeted policies, programs, and education and public awareness activities necessary to reach the goals set forth in *Healthy Chicago*. I look forward to working with all maternal and child health stakeholders to build on our successes and ensure the health and well-being of all Chicago mothers and babies.

Bechara Choucair, M.D.  
Commissioner of Public Health

## HIGHLIGHTS

This epidemiologic report presents statistics related to births in Chicago over the 11-year period 1999 to 2009. Counts, rates, and percentages are presented by maternal demographic characteristics (e.g., age, race-ethnicity, education, marital status), maternal health and healthcare services utilization (e.g., medical risk factors, prenatal care, method of delivery) and infant health characteristics (e.g., gestational age, birthweight, plurality, abnormal conditions). The tables and figures provide evidence of trends and relationships between variables, and are intended to support healthcare and public health professionals and organizations concerned with perinatal health in the development of policies and programs, grant writing, and advocacy. It is also hoped that the data will generate hypotheses for local research on maternal and child health issues.

In 2009, 44,441 **births** were reported to Chicago female residents, a decrease of 12% from 1999. Birth and fertility rates also declined overall, but this trend was not seen across all racial-ethnic groups. **Birth and fertility rates** increased for non-Hispanic (NH) whites, though the rates remained higher for Hispanics and NH blacks throughout the 11-year period. The **teen birth rate** decreased 33% from 1999 to 2009, but Chicago's rate is still one-and-a-half times that of the United States. The teen birth rates for Hispanics and NH blacks are higher than those in NH Asians and NH whites. The **birth rate for women aged 35-44 years** has increased more than 40% since 1999. Rates have risen most in NH Asian and NH white populations, modestly in Hispanics and remained level in NH blacks. Similarly, the mean age at first birth has also increased from 1999 to 2009 by 2 years (23.5 to 25.5). An increase was observed in all four of Chicago's largest racial-ethnic groups.

More than half of all births to Chicago residents were to **unmarried women** in 2009. While national estimates of births to unmarried women have increased steadily over time, the percentage in Chicago has not changed substantially in recent years. The Chicago percentage for 2009 is 20% higher than that of the U.S. overall (see Table 1). There are substantial differences in marital status among mothers by race-ethnicity. Almost 85% of births to NH black women were to unmarried women, while less than 15% of births to NH Asian and NH white women were to unmarried women. The percentage of births to Hispanic women who were unmarried increased by 25% from 1999 and 2009.

**Cigarette smoking during pregnancy** decreased by more than half between 1999 and 2009, to 3.8%. Smoking was reported most frequently among 20-24 year old women (5.4%) and NH black women (9%). Reported smoking rates were below 1% for births to Hispanic and NH Asian women.

The percentage of births to **women who initiated prenatal care in the first trimester of pregnancy** increased by more

than 10% between 1999 and 2009, to 84.3%. This increase was seen in all four racial-ethnic groups. This proportion exceeded the Healthy People 2020 target of 77.9%.<sup>1</sup> In 2009, NH white women had the highest proportion of births for which prenatal care was initiated in the first trimester (92.6%) and NH blacks had the lowest (75.6%). Initiation of prenatal care also differed by age of mother. Mothers aged 35-44 years had percentages 26% higher than teens aged 15-19 years. The percentage of women receiving **early and adequate prenatal care** during their pregnancy also increased between 1999 and 2009 to 74.2%, an increase of 18%. Hispanic, NH Asian and NH white women reached similar levels by 2009, while the estimate for NH blacks was 10 percentage points lower.

The rate of **Cesarean delivery** increased by more than 50% between 1999 and 2009, to 28.7%. This trend is seen nationally, though Chicago's 2009 rate was less than that of the U.S.<sup>2</sup> In Chicago, Hispanics had the lowest rate of Cesarean deliveries (26.1 per 100 births). The rates for NH Asian, NH black and NH white births are slightly higher at 30 per 100 births. By age group, the rate of Cesarean deliveries is highest for 35-44 year old mothers and lowest for 15-19 year olds.

The rate of **twin births** has steadily been increasing since 1999 to 3.6 per 100 births in 2009. NH whites have the highest rates of twin births at 5.7%, and Hispanics have the lowest rate (2.1%). The highest rate of twin births is seen in women aged 35-44 years old (6.0%).

**Low birthweight** births declined overall by 4% between 1999 and 2009, to 9.7%. NH blacks had the highest rate of low birthweight births (14.7%), about double that of Hispanics and NH whites. Among singleton births, rates of low birthweight births decreased more rapidly (10%) between 1999 and 2009, to 7.5%.

Preterm birth (births at less than 37 weeks gestation) is a major risk factor for infant mortality and morbidity. An estimated one-third to 75% of infant deaths are attributable to preterm birth. Respiratory, neurodevelopmental, gastrointestinal and behavioral problems are consequences of preterm birth that affect the infant and can extend into adulthood. Nationally, rates of preterm birth are increasing. Interventions aimed at mitigating and reversing this trend, such as improved prenatal care, nutritional supplementation and treatment of infections, have had a limited impact.<sup>3-8</sup>

Overall, the proportion of **births delivered preterm** declined slightly (4%) between 1999 and 2009, to 10.8%. However, this trend was not seen in all racial-ethnic groups. The highest rates of preterm birth were seen for mothers aged 35-44 years old (13.3%) and NH black women (14.6%). Overall in 2009, Chicago had a lower rate of preterm birth than the U.S. and exceeded the Healthy People 2020 target.<sup>1,2</sup> Among singleton births, rates of preterm births also decreased more rapidly (12%) during the 11-year study period, to 8.5%.

**Table 1. Selected natality indicators for Chicago and the United States, 1999 and 2009, with Healthy People 2020 baselines and targets**

Indicators	Chicago		United States <sup>2,10</sup>		Healthy People 2020 <sup>1</sup>	
	1999	2009	1999	2009	Baseline	Target
Number of births	50,534	44,441	3,959,417	4,130,665	--	--
Crude birth rate (per 1,000 males and females)	17.4	16.4	14.5	13.5	--	--
General fertility rate (per 1,000 females aged 15-44 years old)	71.6	67.2	65.9	66.7	--	--
Total fertility rate (per 1,000 females aged 10-49 years old)	2,107	1,936	2075	2,007	--	--
Teen birth rate (per 1,000 females aged 15-19 years old)	85.2	57.0	49.6	39.1	See footnote	
Percent of births that are the first birth for mother	31.5	34.5	40.1	41.0	--	--
Mean age of women at first birth	23.5	25.5	24.8	25.2	--	--
Percentage of births to unmarried woman	52.6	51.9	33.0	41.0	--	--
Percentage of births delivered by Cesarean	18.4	28.7	22.0	32.3	See footnote	
Percentage of births delivered preterm	11.3	10.8	11.8	12.2	12.7	11.4
Percentage of births delivered very preterm	2.6	2.2	2.0	2.0	2.0	1.8
Percentage of births delivered at low birthweight	10.1	9.7	7.6	8.2	8.2	7.8
Percentage of births delivered at very low birthweight	2.3	1.9	1.5	1.5	1.5	1.4
Percentage of births that are twin births	2.8	3.6	2.9	3.3	--	--
Percentage of births to women with chronic hypertension	0.6	1.7	0.7	1.3	--	--
Percentage of births to women with pregnancy-associated hypertension	2.5	3.2	3.8	4.1	--	--
Percentage of births to women not reporting smoking during pregnancy	91.3	96.0	86.2	NA	89.6	98.6
Percentage of births with prenatal care initiated in the first trimester	74.2	84.3	83.2	NA	70.8	77.9
Percentage of births to women receiving at least adequate prenatal care	63.1	74.2	NA	NA	70.5	77.6

This Healthy People 2020 objective and related baseline and target is measured differently than those calculated for Chicago from birth certificate data. Healthy People 2020 objectives address adolescent pregnancies, not just births, and use the Abortion Provider Survey and the National Survey of Family Growth in addition to the National Vital Statistics System. For births delivered by Cesarean, Healthy People 2020 focuses on births in low-risk (full-term, singleton, vertex presentation) women using data from the 2003 revision of the U.S. Standard Certificate of Live Birth. CDPH was unable to identify low-risk women from birth certificates because Illinois began registering births using the 2003 revision of the U.S. Standard Certificate of Live Birth in 2010.

The results from this report indicate that although progress has been made in many areas of maternal and infant health, disparities persist and work is still needed to further decrease rates of teen births, preterm births and low birthweight births by improving access to and utilization of interconceptional and prenatal care in Chicago and providing better education and support for adolescent health. To that end, the Chicago Department of Public Health (CDPH) has outlined policies, programs and educational and public awareness strategies in *Healthy Chicago* to reduce the rates of teen births, infant mortality and low birthweight births by 10%.<sup>3</sup>

In 2011, CDPH established the Teen Pregnancy Prevention Initiative in collaboration with Chicago Public Schools (CPS) to reduce pregnancy rates and increase healthcare opportunities by empowering adolescents to use medically-accurate information, find youth-friendly healthcare providers, and make safe, healthy and responsible choices. CDPH also facilitates a group of health and policy experts who are working together to develop an action plan for adolescent health, advance comprehensive sex education policies, implement condom availability programs in CPS high schools, and develop public awareness strategies to engage and inform all Chicagoans about adolescent health.

Since 1993, the Family Case Management Program, part of the Women and Children's Health Division at CDPH, has worked to reduce infant mortality in Chicago by ensuring pregnant women have access to and receive prenatal care throughout their pregnancy; ensuring children have access to and receive well child care and Early and Periodic Screening, Diagnosis and Treatment Program visits; and identifying and resolving service barriers and coordinating care. Public health nurses make almost 15,000 home visits annually to pregnant women and new mothers, and provide education on family planning and interconceptional care.

## TECHNICAL NOTES

### Data Sources

The Chicago Department of Public Health (CDPH) generated the tables and figures using geocoded annual birth certificate datasets supplied by the Illinois Department of Public Health (IDPH). These datasets are comprised of data for registered births to women who resided in Chicago at the time of birth. During 1999-2009, the 1989 revision of the U.S. Standard Certificate of Live Birth was used in Illinois (see Figure 11). Geocoding is the process of using location data, such as street address, to determine associated geographic identifiers, such as latitude and longitude, postal code, or community area. Births classified as Chicago but for which the census tract of residence is located outside the city limits were excluded; this resulted in the exclusion of approximately one out of every 5,000 births. The source of annual population estimates for racial-ethnic groups and Chicago community areas was a linear interpolation of counts from the 2000 and 2010 United States Census.<sup>1</sup> Population counts from the 2000 U.S. Census were used for the year 1999.

### Limitations of Birth Certificate Data

The reliability and validity of the data originating from birth certificates has been researched previously by comparing birth certificate data with other types of medical records. These studies have demonstrated the accuracy of many variables, such as those related to demographics, birth outcomes (e.g., birthweight, gestational age, Apgar score) and method of delivery. Others, such as prenatal care, tobacco use, medical risk factors and abnormal conditions of the infant have been found to be less accurate. The extent to which these and other variables are unreliable vary from study to study, and may be due to under- or over-reporting. The validity of reports of infrequent events (e.g., congenital anomalies) is generally lower than reports of frequent events. Standardization of data collection and increasing levels of training and education of hospital staff responsible for collecting and completing birth certificates are cited as ways to increase the reliability and validity of birth certificate data.<sup>2-6</sup>

Both U.S. Census data tables and the birth certificate datasets provided by IDPH contain data for race and Hispanic ethnicity, but the categorization of race differs. U.S. race categories facilitate the recording of multiple races. The birth certificate dataset has one variable for mother's race; although it contains "other" categories (i.e., "other non-white," "other Asian," "unknown"), the categories are not directly comparable with those used by the U.S. Census. This discrepancy could result in some mothers who would be classified as multiracial using U.S. Census categories being recorded as non-Hispanic (NH) Asian, NH black or NH white. Subsequently, the calculated crude birth rates, general fertility rates, total fertility rates and teen birth rates may be artificially higher for these racial-ethnic

groups in Chicago than in jurisdictions outside of Illinois using a means of categorizing mothers' race that is more similar to the one used by the U.S. Census.

### Data Reporting

The guidelines for primary data suppression utilized in this report are based on the value of both the event (numerator) and population or group size (denominator). Data are not reported when the population or group size is between 10 and 29, inclusive, and the difference between the number of events and population or group size is between 1 and 5, inclusive. Data are also not reported when the population or group size is less than 10 and the number of events is between 1 and 9, inclusive. Secondary suppression was used when necessary. Suppressed data is indicated by an “–” in the tables.

The annual number of births to residents of certain Chicago community areas is less than 100. To enhance the reliability of estimates and comparisons, in this report, community area-level counts are aggregated for 2005-2009 for the calculation of rates, percentages and confidence intervals, and an average annual count is provided. Several natality indicators are available by community area for individual years via the City of Chicago Open Data Portal.<sup>7</sup>

Confidence intervals were only calculated for rates and percentages by community area in this report per CDPH's procedure for data dissemination of public health events by geographic units smaller than the city (e.g., community areas). Procedures differ for calculating confidence intervals for rates and percentages, and also differ depending on the number of births on which these statistics are based. CDPH used the methods described in a 2000 publication from the National Center for Health Statistics.<sup>8</sup>

Throughout this report – in all titles, tables and figures – the term “births” is synonymous with “live births.”

### Definitions for Selected Indicators<sup>9</sup>

The **crude birth rate** is the number of live births to resident mothers in a specified geographic area, divided by the total population for the same geographic area for a specified time period resulting in a fraction, which is then multiplied by 1,000. The “population at risk” of giving birth to a live neonate is poorly represented by the total population. As a result, the crude birth rate is affected by the demographic distribution of the population in the denominator, especially by sex and age, but also by race or ethnicity category and other demographic characteristics. There are other fertility measures that are more specific to the population-at-risk and more comparable across time and geography, such as the general fertility rate.

An **age-specific birth rate** is the number of live births to resident women in a specific age group in a specified geographic area, divided by the total female population in the same age group for the same geographic area and time period multiplied by 1,000. The **teen birth rate** refers to mothers aged 15-19

years. The teen birth rate should not be confused with the [percent of births to teens](#) which is the number of births to teens in an area divided by the total number of births in the area and multiplied by 100.

The [total fertility rate](#) is the sum of the age-specific birth rates for 5-year age groupings of female residents between 10

and 49 years from a specified geographic area during a specified time period (usually a calendar year) multiplied by 5. The total fertility rate is an estimate of the number of children 1,000 women would bear in their lifetime if they experienced the same age-specific birth rates as those in the specified geographic area for the specified time period.

			None ..... 00 <input type="checkbox"/>
			Other ..... 09 <input type="checkbox"/>

The **general fertility rate** is the number of resident live births for a specified geographic area divided by the female population aged 15-44 years for the same geographic area and time period resulting in a fraction, which is then multiplied by 1,000. The numerator includes all live births and not just those that occurred to women aged 15-44 years. The use of age 15-44 years for fertility is a common convention because it represents the primary childbearing years.

The **Adequacy of Prenatal Care Utilization (APNCU) Index<sup>10</sup>** incorporates both the timing and quantity of prenatal care visits. The adequacy of prenatal care initiation is determined from the month prenatal care began:

- Adequate Plus: Prenatal care began in 1<sup>st</sup> or 2<sup>nd</sup> month of pregnancy;
- Adequate: Prenatal care began in 3<sup>rd</sup> or 4<sup>th</sup> month of pregnancy;
- Intermediate: Prenatal care began in 5th or 6th month of pregnancy;
- Inadequate: Prenatal care began in 7th, 8th or 9th month of pregnancy or there was no prenatal care.

The adequacy of the amount of prenatal care received is determined from the ratio of actual number of visits to a healthcare provider from the birth certificate to the expected number of visits based on the guidelines for uncomplicated pregnancies of the American College of Obstetricians and Gynecologists:

- Adequate Plus: 110% or more of recommended prenatal care visits received;
- Adequate: 80-109% of recommended prenatal care visits received;
- Intermediate: 50-79% of recommended prenatal care visits received;
- Inadequate: Less than 50% of recommended prenatal care visits received.

These two sub-indexes are merged to form the APNCU Index, in which prenatal care initiated after the fourth month of pregnancy or a mother receiving less than 50% of the recommended prenatal care visits is categorized as Inadequate. All other categories require prenatal care beginning by the fourth month and mimic the scale for the percentage of recommended prenatal care visits received. Of note, the APNCU Index only measures the utilization of prenatal care during pregnancy, not the quality of the care.

Weight of child (33)	17	14	21	18	13	8	10	26	9	13	12

\*Calculated from these items on the birth certificate.

### Birth Records on which Specified Items Were Not Given

The number and percentage of birth records for which specified items were not given on the birth certificate and utilized in this report can be found in Tables 66 and 67. If the percentage missing was greater than 1% for multiple years (1999-2009), when calculating percentages, CDPH excluded the missing records from the denominator. An exception is that births to women recorded as Chicago residents, but for which no community area was given, were included in city-wide calculations.

### 95% Confidence Intervals

A confidence interval is a range of values used to describe the uncertainty around a measurement (e.g., rate) and serves as a measure of the variability in the data. Confidence intervals are calculated based on the standard error of the rate, which is based on the rate and the number of events (e.g., births). Most confidence intervals are calculated as 95% confidence intervals by convention. The 95% confidence interval can best be understood in these terms: if the measurement were conducted 100 times, 95 times the true value would be within the calculated confidence interval and 5 times the true value would be either higher or lower than the range of the confidence interval. For example, a crude birth rate of 10 births

per 1,000 population with a lower limit of 8 and an upper limit of 12 means that there is a 95 percent chance that the rate was between 8 and 12 births per 1,000. Conversely, there is a 5 percent chance that the rate was lower than 8 or higher than 12.

Confidence intervals for rates and percentages can be estimated from the actual number of births. Rates and percentages are subject to random error, arising from random fluctuations in the number of births over time or between different populations. The 95% confidence interval reflects the stability of the rates or percentages. A stable rate or percentage is one that would be close to the same value if the measurement were repeated, i.e., if the rate or percentage did not vary greatly from one year to the next. An unstable rate or percentage is one that would vary from one year to the next due to chance alone. Wider confidence intervals in relation to the rate or percentage indicate instability. Narrow confidence intervals indicate stability, and large fluctuations from year to year would not be expected. If differences are observed between stable rates or percentages (those with narrow confidence intervals), then it is likely that the differences represent true variations, rather than random fluctuations in the number of births. In general, if the 95% confidence intervals of two rates or percentages do not overlap, they are likely to be significantly different.

\*Calculated from these items on the birth certificate.

### Disclaimers

IDPH specifically disclaims responsibility for any analysis, interpretations, or conclusions. The population counts used in the rate calculations are estimates, and this potential source of error should be taken into account when considering the precision of the indicators. Error can result from geocoding as a result of inaccurate or incomplete source data (e.g., the recording of a person's residential residence does not include "North" or "South") or discrepancies in the reference data that is used to match addresses to their associated geographies (e.g., a particular street segment is excluded or associated to corresponding geographies incorrectly). This potential source of error should be taken into account when considering the precision of community area measures. Rate, percentage and confidence interval estimates for time periods or maternal demographic subgroups in which fewer than 20 instances of a given outcome (e.g., low birthweight) were reported are unreliable; this instability should also be considered when making comparisons. Methods and data sources may not be identical to those used in CDPH reports published prior to December 2012.
